Autonomous Robot Teams for Planetary Exploration

Robot teams are uniquely well-positioned to:

- Collect distributed measurements
 - Seismology
 - Weather and climate
 - Ground-penetrating radar
 - Distributed apertures (in orbit)
- Perform exploration and mapping
- Provide system-level resilience

Current operations paradigms do not scale: autonomy is enabling

Multi-agent systems enable high-priority science

jpl.nasa.gov

CADRE's Goal

DEMONSTRATE FIRST AUTONOMOUS EXPLORATION AND DISTRIBUTED MEASUREMENT WITH A TEAM OF ROVERS ON ANOTHER PLANETARY BODY

Lunar Technology Demonstration

- CADRE is a flight technology demonstration manifested as a payload on CP11 (CLPS)/ Intuitive Machines (IM-3) mission, targeting launch in the next year on Falcon-9.
- CADRE is funded from Space Technology Mission Directorate (STMD) under Game Changing Development (GCD).
- Destination: Reiner Gamma is known for its mysterious lunar swirls, where dark and light regolith mix.
- Three rovers will work together to explore the surface nearby during a single Lunar day (about 10 Earth days).

From concept to flight project

Raising the TRL

NASA Technology Readiness Levels

- TRL 1: What if there were Unicorns
- TRL 2: We have drawn a Unicorn
- TRL 3: unicorn_v8_final_final.cad
- TRL 4: We have placed a horn on a horse in our lab
- TRL 5: We took the horse outside
- TRL 6: We're now calling the horse a Unicorn
- TRL 7: We're pretty sure the Unicorn might survive if we launch it into space TRL 8: omg it survived
- TRL 9: Our reference design incorporates high-heritage Space Unicorns

Technology Development

Development of a small rover with unique mobility capabilities (PUFFER) Development of multi-agent autonomy for cooperative exploration in unmapped environments (A-PUFFER) Demonstration of multi-agent autonomy on the Moon (CADRE)

Game Changer: Access to Science-Rich Extreme Terrains

NASA/JPL-Caltech/MSSS: https://mars.nasa.gov/resources/7507/curiosity-self-portrait-at-big-sky-drilling-site/

Eroded Rock Features

Steep Stratified Slopes

Surface and Subsurface Features

Lunar Pit NASA/GSFC/Arizona State University, http://lroc.sese.asu.edu/images

PUFFER Capabilities

- Small, foldable robotic platforms for <u>accessing extreme terrain</u> (steep slopes, low clearance overhangs).
- Low- mass, volume, cost to enable deployment of <u>larger</u> <u>number of rovers per mission</u>.
- New multi-rover autonomy to achieve <u>scalability</u>, <u>"strength in</u> <u>numbers"</u>

Importance

- Foldable robotic platforms with <u>high</u> <u>stowed-to-deployed ratios</u>, <u>but scalable</u> <u>on-demand</u>
- Success in high-risk (high-uncertainty) extreme environments with limited comms via <u>hands-off autonomy</u>
- Provides quicker-to-develop, lower-cost <u>COTS solutions to flight</u> (à la MarCOs, Mars Heli)

Progression of PUFFER Prototypes

"Snow PUFFER" - 2017

2018

v3.5 - 2019

Average roundtrip lightspeed latency to Earth, in minutes

Autonomy enables multi-agent exploration

21

- 1. Multiple PUFFERs map an unstructured area
- 2. PUFFERs operate autonomously and share local maps and other data with base station when communication is available
- 3. Base station constructs global map by merging all robots' local maps
- 4. Base station sets individual robot targets for exploration or science measurements
- 5. PUFFERs use local information and current global map (if available) to navigate to those targets

Solitary autonomy at first...

..., but then with more PUFFERs!

Cooperative Exploration in Action

Going to space

Mission Overview

- CADRE (Cooperative Autonomous Distributed Robotic Exploration) is a NASA STMD Game Changing Development (GCD) project to advance multi-agent autonomy and demonstrate it on the Moon.
- CADRE is manifested as a payload on Intuitive Machine's IM-3 mission, and is headed to Reiner Gamma (Moon's equatorial region)
- CADRE's technology demonstration will focus on cooperative exploration and distributed measurements using multiple ground penetrating radars (GPRs).

Building this for space!

System Overview

Rover Overview

Cooperative Distributed Measurements

Today.

Single Monostatic Measurements

2-DIMENSIONAL DATA ONLY

STATE OF THE ART:

Chang'e 3 and 4 **Lunar Penetrating Radar** on the Moon Perseverance **RIMFAX** on Mars Zhurong **Lunar Penetrating Radar** on Mars **Objective**.

Distributed & Adaptable Multi-Static Measurements

3D SUBSURFACE IMAGERY FROM MULTIPLE GPRs WORKING TOGETHER

 Rovers have to navigate across the lunar surface in a specific formation (separation dictates measuring depth) and maintain this formation within a certain threshold (derived from required SNR)

The Autonomy Stack

Ground operators *Which region to explore?*

Planning, Scheduling & Execution *Where do we go now?*

Obstacle Feam Planner Trajectory Local Planne Horizon Global Planner Horizon Guidance, Navigation & Control How do I get there?

37 jpl.nasa.gov

Software Architecture

- Sensors in the flight hardware are handled by the flight software (written in F'), as well as, other core capabilities, such as communication
- Autonomy components are implemented in C++, integrated with F', and run on the ModalAI VOXL computer running non-realtime Linux
- Autonomy architecture is hybrid, where planning is centralized on an elected leader, while execution is distributed.

Communications

NASA

- Mesh communication protocol between rovers, lander
- TCP-IP interface

Planning, Scheduling, and Execution

Architecture

1. How do we coordinate?

- 2. Who (if any) is the leader?
- 3. Where are the decisions made?

Algorithms

4. When do we drive, and when do we sleep?

5. How do we explore a region together?

6. How do we perform a distributed measurement?

Coordination Architectures

Electing a leader

a) Minimum Spanning Tree using GHS algorithm *Intuition*: recursively merge trees log(n) times.

- 0. Everyone is root (■) and leaf (▲) of own one-node subtree
- 1. Ping neighbors to find edge cost, send to root along own subtree's MST
 - 2. Nearest* neighbor subtrees merge *defined by edge cost
 - 3. Repeat up to log(n) times

- b) Tree root monitors leader health, nominates next leader
 - Tree root is not necessarily the leader
 - Decouple (i) finding a unique agent from (ii) finding the best leader

Distributed: "divide and conquer"

Centralized

58 jpl.nasa.gov

	"Divide and Conquer"	"All in one"
Performance	Looser coupling between team and node planner can result in suboptimal performance, No communication relays	Better performance, closer to optimality Can accommodate communication relays
Information Exchange	Significantly less coordination required	Requires more information from agent to team planner, more often
Operability	Easier to interpret Every node has a clear role 	 Harder to interpret "Why are nodes going back and forth across the workspace?"
	 Coordination is laborious (latency, network reliability, stale data, etc.), that is where things can go wrong 	 Tighter coupling between team and node planner: closer to optimum More frequent team-level decisions

• More frequent team-level decisions incorporate new information as it is available

Where are the decisions made?

Ground

• Provides region to explore

Leader

 Computes sub-regions for each robot

Each robot

• Explores its own region

Distributed: "divide and conquer"

Distributed Measurement and GPR

63 jpl.nasa.gov

Distributed Measurement

- Sampling-based planner is used to plan formation (with allowable deviation) through map
- RRT* output is adjusted to smooth motion and solution density
- Paths are timestamped to create trajectories and given tolerances ("tubes") given timespace constraints needed for GPR
- Surface mobility motion planners plan within tubes (and signal fault to leader if unable)

Distributed Measurement

Distributed Measurement

	Deliberative Planning	Formation Control
Performance	Can explicitly enforce formation constraint	Best-effort formation maintenance
Computational Complexity	Higher (planning in the robots' joint space)	Low (closed-loop control)
Information Exchange	Infrequent communication from agents to leader	Requires continuous information exchange between all agents
Operability	Single source of authority for cooperation, no reliance on emergent behavior	Reliant on emergent behavior (e.g. in presence of obstacles)

- Higher computation complexity
- Explicitly enforces formation control constraint
- Lower communication burden

- Tighter control loop
- Relies on emerging behavior to maintain formation while going around obstacles
- Agent-to-agent communication

Putting it all together

Recent Results

- <u>FMs cooperatively and autonomously</u> <u>completed a successful formation drive (as</u> they would for a distributed measurement)
 - Base station executed leader functionality by planning and scheduling for the team
- When driving out-of-formation, rovers reported to leader and the system <u>replanned</u> and continued drive automatically
 - Three (3) full (autonomous) planning cycles were performed
 - A second experiment verified that <u>the team</u> stops driving when any rover violates its <u>SoC constraint</u> (i.e., battery too low)
 - A third experiment included a previously unmapped obstacle around which the team replanned.
- Operators started autonomy, but <u>did not</u> <u>intervene at any point</u>.

Cooperative Autonomous Distributed Robotic Exploration (CADRE)

Summary

CADRE VALIDATES A NEW GENERATION OF ROBOTIC TECHNOLOGIES:

- Small-scale, autonomy capable rovers
- Multi-agent autonomy that enables robots to work cooperatively as a team (requires localization!)
- Ability to perform distributed science measurements
